Single-Source Shortest Path Problem

The problem of finding shortest paths from a source vertex v to all other vertices in the graph.

Dijkstra's algorithm

a solution to the single-source shortest path problem in graph theory.

Works on both directed and undirected graphs. However, all edges must have nonnegative weights.

Approach: Greedy

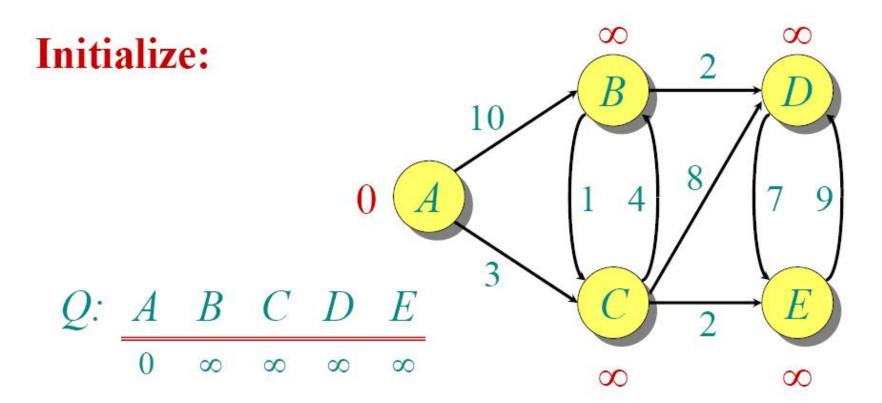

Input: Weighted graph $G=\{E,V\}$ and source vertex $v\in V$, such that all edge weights are nonnegative

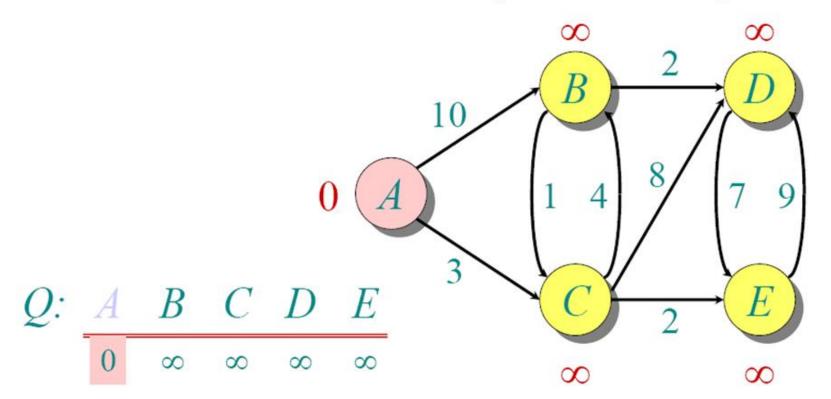

Output: Lengths of shortest paths (or the shortest paths themselves) from a given source vertex *v*∈V to all other vertices

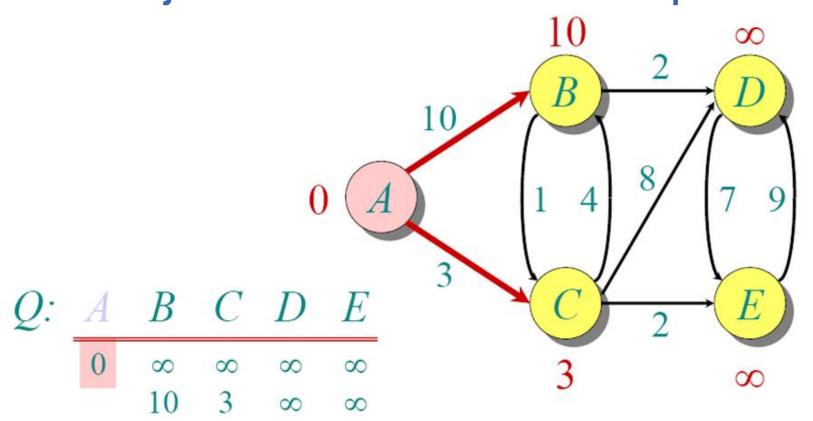

Dijkstra's algorithm - Pseudocode

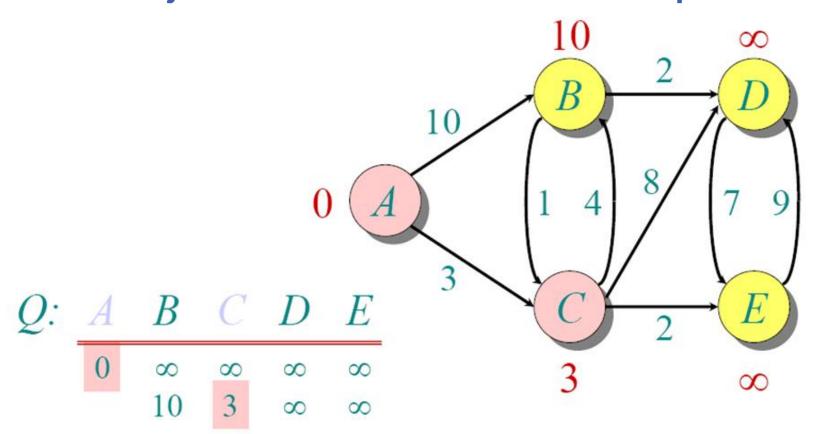

```
(distance to source vertex is zero)
dist[s] \leftarrow 0
for all v \in V - \{s\}
     do dist[v]\leftarrow \infty
                                     (set all other distances to infinity)
                                     (S, the set of visited vertices is initially empty)
S←Ø
                                     (Q, the queue initially contains all vertices)
Q←V
while Q ≠Ø
                                     (while the queue is not empty)
do u \leftarrow mindistance(Q, dist)
                                     (select the element of Q with the min. distance)
                                     (add u to list of visited vertices)
    S \leftarrow S \cup \{u\}
    for all v \in neighbors[u]
         do if dist[v] > dist[u] + w(u, v)
                                                        (if new shortest path found)
                then d[v] \leftarrow d[u] + w(u, v)
                                                        (set new value of shortest path)
                   (if desired, add traceback code)
```

return dist

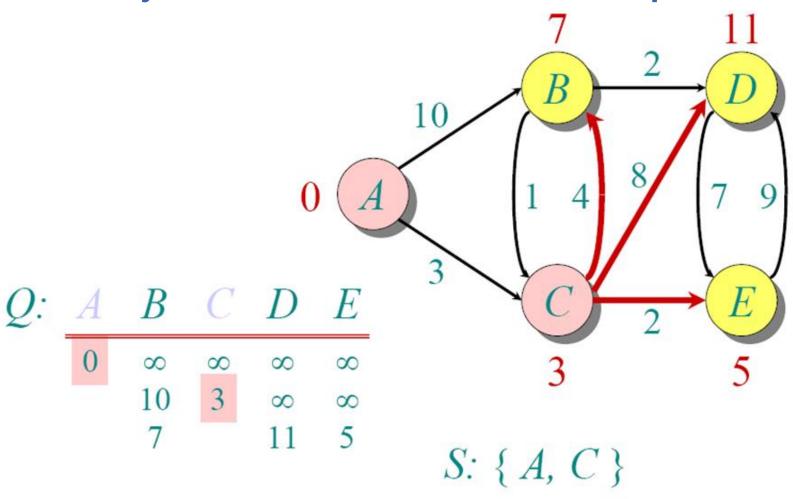

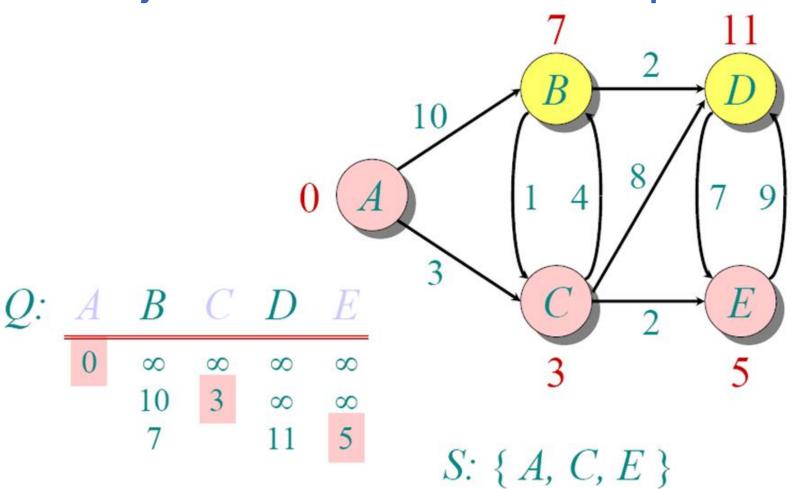

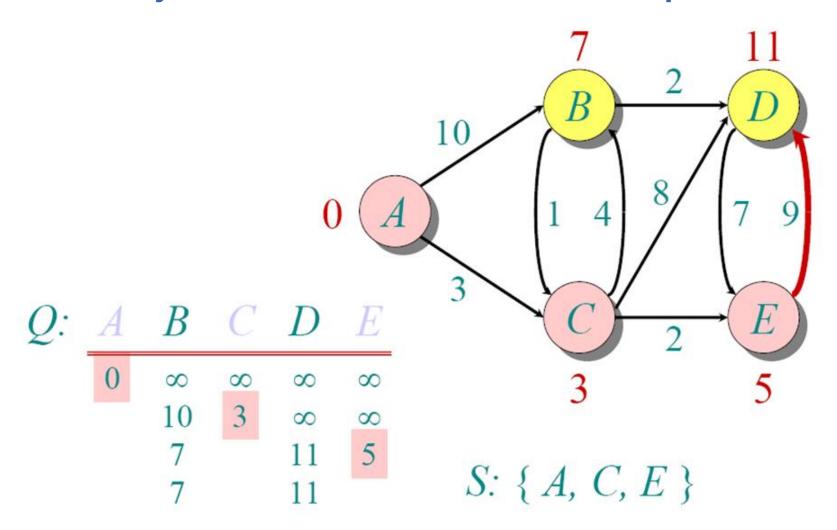

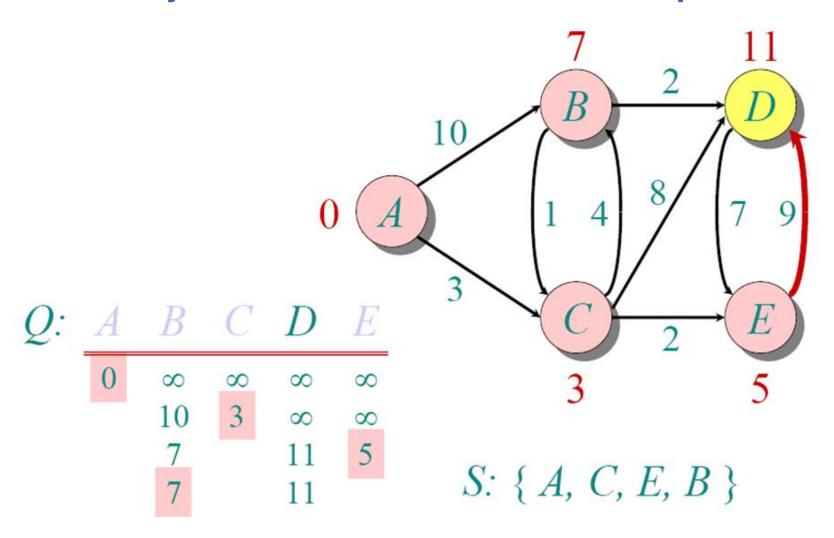

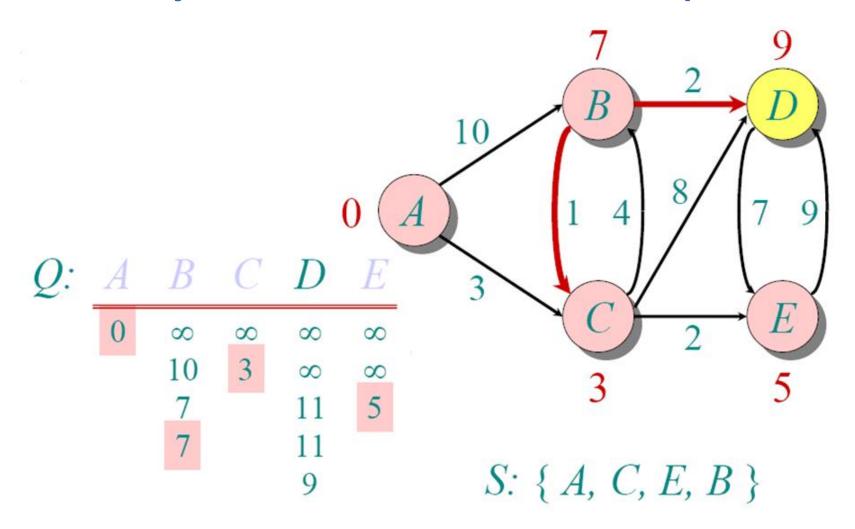

S: { A, C }

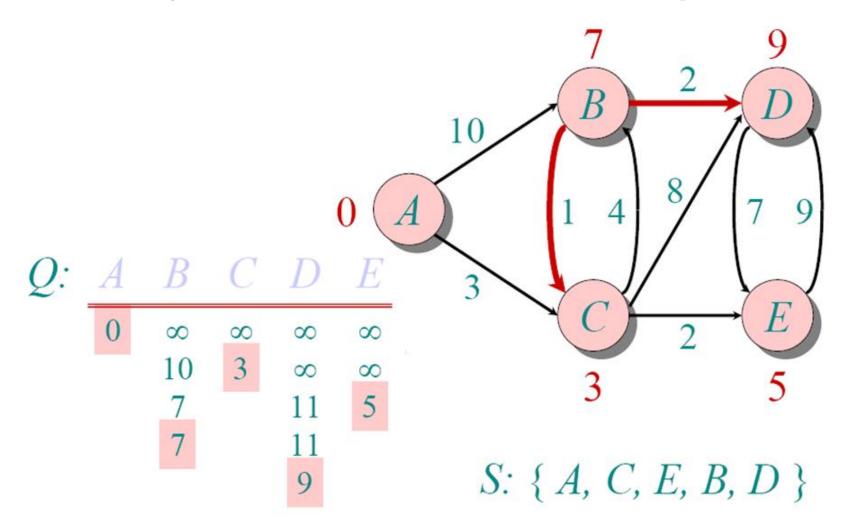

Implementations and Running Times

The simplest implementation is to store vertices in an array or linked list. This will produce a running time of

$$O(|V|^2 + |E|)$$

For sparse graphs, or graphs with very few edges and many nodes, it can be implemented more efficiently storing the graph in an adjacency list using a binary heap or priority queue. This will produce a running time of

$$O((|E|+|V|)\log |V|)$$

•DIJKSTRA'S ALGORITHM - WHY USE IT?

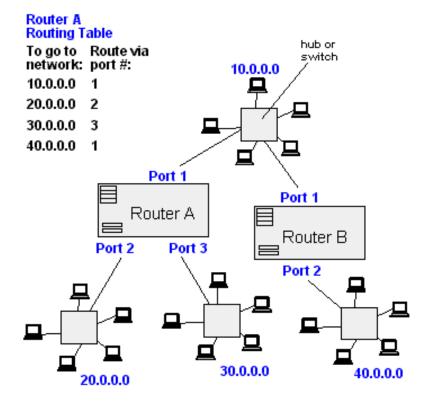

- As mentioned, Dijkstra's algorithm calculates the shortest path to every vertex.
- However, it is about as computationally expensive to calculate the shortest path from vertex *u* to every vertex using Dijkstra's as it is to calculate the shortest path to some particular vertex *v*.
- Therefore, anytime we want to know the optimal path to some other vertex from a determined origin, we can use Dijkstra's algorithm.

Applications of Dijkstra's Algorithm

- Traffic Information Systems are most prominent use
- Mapping (Map Quest, Google Maps)
- Routing Systems

A Minimum Spanning Tree (MST)

- a subgraph of an <u>undirected graph</u> such that
 - the subgraph spans (includes) all nodes,
 - is connected,
 - is acyclic,
 - and has minimum total edge weight

Minimum Spanning Trees

Prim's Algorithm

• Similar to Dijkstra's Algorithm

Kruskal's Algorithm

• Focuses on edges, rather than nodes

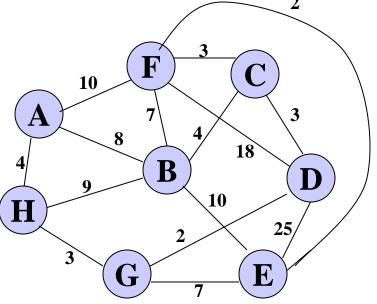

Algorithm Characteristics

- Both Prim's and Kruskal's Algorithms work with undirected graphs
- Both work with <u>weighted</u> and <u>unweighted</u> graphs but are more interesting when edges are weighted
- Both are <u>greedy</u> algorithms that produce optimal solutions

Prim's Algorithm

• Similar to Dijkstra's Algorithm except that d_v records edge weights, not path lengths

Kruskal's Algorithm

- Work with edges, rather than nodes
- Two steps:
 - Sort edges by increasing edge weight
 - Select the first |V| 1 edges that do not generate a cycle

Walk-Through

Consider an undirected, weight graph

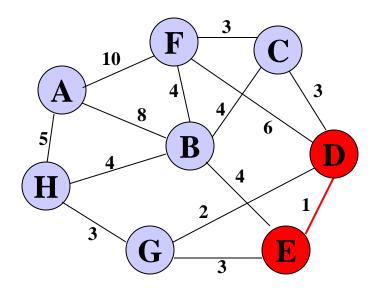

Sort the edges by increasing edge weight

Kruskal's Algorithm

```
Let G = (V, E) be the given graph, with |V| = n
        Start with a graph T = (V, \phi)
        consisting of only the vertices of G and no edges;
        /* This can be viewed as n connected components,
            each vertex being one connected component */
        Arrange E in the order of increasing costs;
         for (i = 1, I \le n - 1, i + +) {
                Select the next smallest cost edge;
                if (the edge connects two different connected components)
                      add the edge to T;
```
